

Valuation Generalization Under Location Shift

Change measured as Location-Grouped CV minus Random CV. This is the change when moving from random evaluation to evaluation on held-out locations.

Folds are not paired between regimes: the two regimes use different splits, so intervals use the independent-samples Welch Satterthwaite formula on the difference of fold means, not a paired t-difference. A positive change indicates worse performance under location hold-out for error metrics; a negative change in R² indicates the same. Models are shown in a fixed pre-declared display order, not sorted by value.
